

CHIEF COMPLAINT: 1. Stage IIIC endometrial cancer. 2. Adjuvant chemotherapy with cisplatin, Adriamycin, and Abraxane.

HISTORY OF PRESENT ILLNESS: The patient is a 47-year-old female who was noted to have abnormal vaginal bleeding in the fall of 2009. In March 2010, she had an abnormal endometrial ultrasound with thickening of the endometrium and an enlarged uterus. CT scan of the abdomen on 03/22/2010 showed an enlarged uterus, thickening of the endometrium, and a mass structure in the right and left adnexa that was suspicious for ovarian metastasis. On 04/01/2010, she had a robotic modified radical hysterectomy with bilateral salpingo-oophorectomy and appendectomy with pelvic and periaortic lymphadenectomy. The pathology was positive for grade III endometrial adenocarcinoma, 9.5 cm in size with 2 cm of invasion. Four of 30 lymph nodes were positive for disease. The left ovary was positive for metastatic disease. Postsurgical PET/CT scan showed left lower pelvic side wall seroma and hypermetabolic abdominal and right pelvic retroperitoneal lymph nodes suspicious for metastatic disease. The patient has completed five of planned six cycles of chemotherapy and comes in to clinic today for followup. Of note, we had sent off genetic testing which was denied back in June. I have been trying to get this testing completed.

CURRENT MEDICATIONS: Synthroid q.d., ferrous sulfate 325 mg b.i.d., multivitamin q.d., Ativan 0.5 mg q.4 hours p.r.n. nausea and insomnia, gabapentin one tablet at bedtime.

ALLERGIES:
