

ALLOWED CONDITIONS:, 726.31 right medial epicondylitis;
354.0 right carpal tunnel syndrome.,CONTESTED
CONDITIONS:, 354.2 right cubital tunnel
syndrome.,EMPLOYER:, ABCD, ,I examined Xxxxx today for
the allowed conditions and also the contested conditions
listed above. I obtained her history from company medical
records and performed an examination. She is a 38-year-old
laborer who states that she was injured on April 26, 2006,
which according to the FROI (the injury occurred over a period
of time from performing normal job processes such as putting
bumpers on cars, gas caps and doors on cars). She denies
having any symptoms prior to the accident April 26, 2006. She
is right handed. She used a tennis elbow brace, hand
exercises, physical therapy, and Vicodin. She received
treatment from Dr. X and also Dr. Y,DIAGNOSTIC STUDIES:,
June 27, 2006, EMG and nerve conduction velocity right
upper extremity showed a moderate right carpal tunnel
syndrome. No evidence of a right cervical radiculopathy or
ulnar neuropathy at the wrist or elbow. January 29, 2007,
EMG right upper extremity was normal and there was a
normal nerve conduction velocity. At the time of the
examination, she complained of a constant pain in the
olecranon and distal triceps with tingling in the right long, ring
and small fingers, and night pain. The pain was accentuated
by gripping or opening the jar. She is taking four Aleve a day
and currently does not have any other treatment.,RECORDS
REVIEWED: , Injury and illness incident report, US
Healthworks records; Z physician review; Y office notes; X

office notes who noted that on examination of the right elbow that the ulnar nerve subluxed with flexion and extension of the elbow.,EXAMINATION: , Examination of her right elbow revealed no measurable atrophy of the upper arm. She was markedly tender over the medial epicondyle, but also the olecranon and distal process and she was exquisitely tender over the ulnar nerve. I did not detect subluxation of the ulnar nerve with flexion and extension. With this, she was extremely tender in this area. There is no instability of the elbow. Range of motion was 0 to 145 degrees, flexion 90 degrees of pronation and supination. The elbow flexion test was positive. There is normal motor power in the elbow and also on the right hand, specifically in the ulnar intrinsics. There was diminished sensation on the right ring and small fingers, specifically the ulnar side of the ring finger of the entire small finger. There was no wasting of the intrinsics. No clawing of the hand. Examination of the right wrist revealed extension 45 degrees, flexion 45 degrees, radial deviation 15 degrees, and ulnar deviation 35 degrees. She was tender over the dorsum of the hand over the ulnar head and the volar aspect of the wrist. Wrist flexion causes paresthesias on the right ring and small fingers. Grasp was weak. There was no sign of causalgia, but no measurable atrophy of the forearm. No reflex changes.,QUESTION:, Ms. Xxxxx has filed an application of additional allowance of right cubital tunnel syndrome. Based on the current objective findings, mechanism of injury, medical records or diagnostic studies, does the medical evidence support the existence of the

requested condition?,ANSWER:, Yes. She has a positive elbow flexion test and she is markedly tender over the ulnar nerve at the elbow and also has diminished sensation in the ulnar nerve distribution, specifically in the entire right small finger and the ulnar half of the ring finger. I did not find the subluxation of the ulnar nerve with flexion and extension with Dr. X did previously find on his examination.,QUESTION: , If

you find these conditions exist, are they a direct and proximate result of April 26, 2006, injury?,ANSWER: , Yes. Repeated flexion and extension would irritate the ulnar nerve particularly if it was subluxing which it could very well have which Dr. X objectively identified on his examination.

Therefore, I believe it is a direct and proximate result of April 26, 2006, injury.,QUESTION: , Do you find that Ms. Xxxxx's injury or disability is caused by natural deterioration of tissue, organ or part of the body?,ANSWER: , No.,QUESTION:, In

addition, if you find that the condition exists, are there non-occupational activities or intervening injuries that could have contributed to Ms. Xxxxx's condition?,ANSWER: , It is possible that direct injury to the ulnar nerve at the elbow could cause this syndrome; however, there is no history of this and the records do not indicate an injury of this type.,QUESTION: ,
